A Personality-based Framework for Utterance Generation in Dialogue Applications

François Mairese and Marilyn Walker

{F.Mairesse,M.A.Walker}@sheffield.ac.uk

Abstract
Conversation is an essential component of social behaviour, one of the primary means by which humans express emotions, moods, attitudes and personality. Thus a technical capability for dialogue applications, such as interactive narrative systems (INS), human robot interaction (HRI) and spoken dialogue systems (SDS), is the ability to support natural conversational interaction. However, system utterances in existing systems are typically handcrafted, leading to problems of portability and scalability. We propose a framework for automatically generating language projecting different personality traits based on the ‘Big Five’ model of personality. We show that our PERSONAGE generator can produce utterances with recognisable personality for all Big Five traits, according to human judges. We also test the ability of PERSONAGE to vary the characters’ personality in an existing interactive narrative system, showing that some forms of variation can be automatically obtained in a new domain, depending on the level of utterance representation.

Introduction
Conversation is an essential component of social behaviour, one of the primary means by which humans express emotions, moods, attitudes and personality. Thus a technical capability for dialogue applications, such as interactive narrative systems (INS), human robot interaction (HRI) and spoken dialogue systems (SDS), is the ability to support natural conversational interaction. While INS clearly have the additional technical requirement of producing system outputs that are recognisable as manifesting differences in dramatic character, the quality of the interaction for any dialogue application is affected by the linguistic style of system utterances, even when the application is fundamentally task-oriented (Cassell & Bickmore, 2003; Isbister & Nass, 2000; Walker, Cahn, & Whittaker, 1997; Wang et al., 2005).

In order to support natural conversational interaction, dialogue applications often apply natural language processing to the user’s input to allow users flexibility in what they say to the system (Mateas & Stern, 2003; Pieraccini & Levin, 1995). However, utterances produced by the system, in both INS and SDS, are often highly handcrafted, e.g. sound extracts pre-recorded by actors. Although this approach produces high quality utterances, it suffers from problems of portability and scalability (Walker & Rambow, 2002), or what has been called the authoring bottleneck in the case of INS (Mateas, 2007).

We believe that these problems can be addressed by research on automated methods of utterance generation, based on a spoken language generation (SLG) architecture (Walker & Rambow, 2002). This research could ultimately lead to off-the-shelf tools that would support the creation of interesting dramatic characters and dialogue partners, without the need for a detailed knowledge of underlying SLG implementation details. But the requirement for variation in linguistic style that supports social behaviour suggests that what is needed is a framework for automatically generating character variation in a comprehensive and systematic way, i.e. a method or a theory that quantifies the most important individual differences in behaviour, and the way they affect system linguistic output in dialogic situations.

Philosophers and psychologists have tried to identify important dimensions of human behaviour for hundreds of years, beginning with Theophrastus in Ancient Greece (B.C. 371-287). However, we propose that a natural framework can be found in the somewhat more recent research on personality psychology, which suggests that behavioural differences of human individuals are best categorised in terms of personality traits, which describe consistent patterns in the way individuals behave, feel, and think, and which affect human behaviour in most situations (Allport & Odbert, 1936; Norman, 1963). In fact, Allport, the founder of trait theory, suggests that personality traits are intuitively appealing for modelling different aspects of human behaviour because of their pervasiveness in descriptions of dramatic and literary character (Allport, 1960):

Almost all the literature of character—whether [non-fiction] or fiction, drama or biography—proceeds on the psychological assumption that each character has certain traits peculiar to himself which can be defined through the narrating of typical episodes from life.

Allport’s approach was based on the Lexical Hypothesis, i.e. that any trait important for describing human behaviour has a corresponding lexical token. These lexical tokens are typically adjectives, e.g. trustworthy, modest, friendly, spontaneous, talkative, dutiful, anxious, impulsive, vulnerable, etc. Allport & Odbert (1936) collected 17,953 trait terms from English and identified 4,500 as ‘stable traits’.
### Table 1: Example adjectives associated with the Big Five traits.

Although this eating house’s price is around 41 dollars, the food is rather satisfactory. This eating place, which provides kind of second-rate atmosphere, is a Latin American restaurant, alright?</td>
<td>5.00</td>
</tr>
</tbody>
</table>

This approach led to a great deal of subsequent work over the last century, and a lively debate over the definition of the most essential traits. However, in the last 50 years, a standard framework has emerged of the ‘Big Five’ personality traits (Goldberg, 1990; McCrae & Costa, 1987; Norman, 1963). These traits were obtained empirically by extracting the main components of a factor analysis over adjective descriptors, they are thus considered as the dimensions explaining the most variance of behaviour among people. Table 1 provides a description of each trait.

The Big Five provide a concise framework for characterising the projected personality of conversational agents. A second advantage of this framework is that a large number of validated questionnaires can be used to evaluate human perceptions of system generated utterances (see evaluation section). Furthermore, psychologists have established the relation between the Big Five and other dimensions of expression variation, such as emotion. For example, there are strong relations between the extraversion and conscientiousness traits and the positive affects, and between neuroticism and disagreeableness and various negative affects (Watson & Clark, 1992). Finally, psychologists have documented a number of behavioural markers associated with each dimension, involving many aspects of communication such as language, speech, gesture and facial display. For example, previous research shows that extraverts talk more, louder,
The high-level architecture of the base generator is illustrated in Figure 1, and its generation parameters are shown in Table 3. The first component is the content planner, which specifies the structure of the information to be conveyed by processing a content plan such as in Figure 2. The content plan is a tree in which the utterance’s propositions—e.g., assert(best(X))—are combined using rhetorical relations (e.g., JUSTIFY). The resulting content plan tree is then processed by the sentence planner, which selects syntactic templates for expressing individual propositions and aggregates them to produce the utterance’s full syntactic structure. The pragmatic marker insertion component then modifies the syntactic structure to produce various pragmatic effects, depending on the parameter values and the markers’ insertion constraints. The next component selects the most appropriate lexeme for each content word, given the lexical selection parameters. Finally, the RealPro realiser (Lavoie & Rambow, 1997) converts the final syntactic structure into a string by applying surface grammatical rules, such as morphological inflection and function word insertion. See previous work for a detailed description of the implementation of each component (Mairesse & Walker, 2007).

Figure 1: The architecture of the PERSONAGE generator.

Figure 2: A content plan for a recommendation.

Human perceptual evaluation of the Big Five traits

Methodology

Our primary hypothesis is that language generated by varying linguistic parameters identified by research on the Big Five can be recognised as expressing that specific trait. As a

Table 3: PERSONAGE’s generation parameters, implementation details can be found in (Mairesse & Walker, 2007).

proof of concept, we first test the hypothesis that personality can be made manifest in evaluative speech acts that recommend or compare domain entities, such as restaurants or movies (Isard, Brockmann, & Oberlander, 2006; Stent, Prasad, & Walker, 2004). The first instantiation of our generator targets a database of restaurants in New York City.1 There are eight attributes for each restaurant: the name and address, scalar attributes for price, food quality, atmosphere, and service and categorical attributes for neighbourhood and type of cuisine.

Two expert judges evaluate a set of generated utterances as if they had been uttered by a friend responding in a dialogue to a request to recommend restaurants. These utterances systematically manipulate parameters related to each trait, e.g. one utterance is generated with the neurotic parameter setting, another with the emotionally stable parameters. We set ourselves the hard task of asking judges to make perception judges of personality on the basis of a single utterance, although in most applications, personality perceptions could emerge over the course of the dialogue. The judges rate the personality of each utterance by completing the Ten-Item Personality Inventory, as this instrument was shown to be psychometrically superior to a ‘single item per trait’ questionnaire (Gosling, Rentfrow, & Swann, 2003). The answers are averaged to produce a rating for each trait ranging from 1 (e.g. highly neurotic) to 7 (e.g. very emo-

1An online demo is available at www.dcs.shef.ac.uk/cogsys/personage.html
tionally stable). The judges rated 200 utterances, grouped into 20 sets of 10 utterances generated from the same content plan, each set containing 2 utterances per trait, with parameter settings for both the low end and the high end of each dimension. Thus, there were a total of 40 utterances for each trait, with each half targeting one extreme of the trait dimension. Table 2 shows the 10 utterances generated from the content plan in Figure 2. The judges rated one randomly ordered set at a time, but viewed all 10 utterances in that set before rating them. To avoid replication of generation decisions, multiple outputs were generated by allowing each parameter setting to be normally distributed with a 15% standard deviation.

Results

To assess whether PERSONAGE generates language that can be recognised as projecting extreme personality, we compare the average ratings of the 20 utterances expressing the low end of each trait and the 20 utterances expressing the high end. Table 4 shows the average personality ratings for each set of utterances, on a scale from 1 to 7. Paired t-tests show that the judges can discriminate between both extreme utterance sets for each trait (p < .001). Introvert utterances have an average rating of 2.96 out of 7 while extravert utterances have an average rating of 5.98 (difference of 3.02). Additionally, if we divide the data into two equal-width bins around the neutral extravert rating (4 out of 7), then PERSONAGE’s utterance ratings fall in the bin predicted by the parameter set 89.2% of the time. Figure 3 shows the distribution of the extraversion ratings over the two sets.

The rightmost column in Table 4 shows that the judges agree significantly for all Big Five traits. The highest agreement occurs for extravert and introvert utterances (r = .73), and the lowest for utterances expressing conscientiousness (r = .42). Such a level of agreement reflects the difficulty of estimating the speaker’s personality through a single utterance.

Emotional stability is the most recognisable trait after extraversion, with a mean rating difference of 2.67 between neurotic and stable utterances. Openness to experience is the hardest trait to project in our domain, with a rating difference of 1.32 between the utterance sets. While the rating distributions of most traits tends to be more positive than the median, ratings for openness to experience are lower on average, showing that PERSONAGE’s utterances tend to project the image of a slightly narrow-minded speaker. While PERSONAGE’s utterances cover the full range for each personality trait (see Figure 3), a recalibration of the parameter settings to attenuate those biases is left to future work.

Generating personality in an interactive narrative

While the previous section shows that recognisable personality can be expressed in the information presentation domain, our intention is that PERSONAGE should be a tool that can be used in other domains, so most of the generation decisions it makes are domain-independent. In this section, we provide examples suggesting that PERSONAGE can project various personality types in a sample dialogue from the Façade interactive narrative system (INS) (Mateas & Stern, 2003).

An important choice faced by INS developers is the level of abstraction of the manipulated language. Façade currently produces pre-recorded prompts, i.e. the variation is hardcoded in each utterance. We investigate deeper representations by manually converting dialogue turns into syntactic structures and modifying them using PERSONAGE’s pragmatic insertion marker and lexical choice components. Tables 5 and 6 show a series of modified dialogues between Trip and Grace, a married couple who the player is visiting for an evening. Each column represents the same initial dialogue, in which both speakers were assigned a different personality.

Although there is no generation at the content and aggregation levels, the amount of variation is still substantial, see Trip changing from an extravert in the third column of Table 5, i.e. ‘Yeah, Grace’s decorating has been such like, a really great outlet for her, you know!’ to a more serious conscientious person in the third column of Table 6, i.e. ‘I see, ok, I suppose Grace’s decorating has been such a rather outstanding outlet for her’. On the other end of the same

For analysis we will be using the term extraversion, which is the first system to clearly demonstrate that personality variation for all of the Big Five personality traits, while in previous work we only evaluated the projection of extraversion (Mairese & Walker, 2007). Thus PERSONAGE is the first system to clearly demonstrate that the Big Five personality traits can be manifested by an automatic generator, to provide system utterances in dialogue applications that require social intelligence. In previous work, Walker, Cahn, & Whittaker (1997) describe a generator intended to affect perceptions of personality, based on Brown and Levinson’s theory of politeness (Brown & Levinson, 1987). The generator uses some of the linguistic constructions implemented here, such as tag questions

**Discussion**

Our results show that PERSONAGE can produce recognisable personality variation for all of the Big Five personality traits, while in previous work we only evaluated the projection of extraversion (Mairese & Walker, 2007). Thus PERSONAGE is the first system to clearly demonstrate that the Big Five personality traits can be manifested by an automatic generator, to provide system utterances in dialogue applications that require social intelligence. In previous work, Walker, Cahn, & Whittaker (1997) describe a generator intended to affect perceptions of personality, based on Brown and Levinson’s theory of politeness (Brown & Levinson, 1987). The generator uses some of the linguistic constructions implemented here, such as tag questions
There are several issues to be addressed before automatic generation can be applied successfully in a range of dialogue applications. One limitation is that so far we have focused only on textual language generation, whereas it would be possible to use the Big Five traits to control other aspects of expressive behaviour (e.g. gesture, dialogue strategy, speech rate, prosody and amplitude). A major issue is the reliance of automated generation on the quality of the text-to-speech (TTS) engine. Only recently has research begun to build off-the-shelf high-quality synthesisers with a large range of speech variation in mind (Trouvain et al., 2006). However there are many markers of personality in speech (Scherer, 1979), thus our approach could be applied to a customisable TTS engine, e.g. associating extraversion with higher amplitude and higher speech rate. While some speech markers can be controlled directly by the TTS engine, others require a careful implementation, such as the variation of pitch across an utterance or the prosody of individual words (e.g. filled pauses). Nevertheless, the current rate of progress in the field suggests that TTS engines will express realistic affect and personality in a short time frame.

Another issue is that PERSONAGE assumes that the communicative goal is given to it as input, and that the expression of this goal is supported by a generation dictionary. Thus PERSONAGE has not been integrated with a planner, and the initial dictionary must be handcrafted. Other research has started to address these limitations (Higashinaka, Prasad, & Walker, 2006; Riedl & Young, 2004).

<td>I see, ok. I suppose Grace’s decorating has been such a rather outstanding outlet for her.</td>
<td>I don’t know mate! Outlet?</td>
<td>I see, Suppose Grace’s decorating has been such a sort of outstanding outlet for her, you know, you see?</td>
<td></td>
</tr>
<tr>
<td>GRACE</td>
<td>Outlet? What do you mean outlet?</td>
<td>Well, i see, I am always encouraging her to buy. Only the best for us.</td>
<td>I don’t know mate! Outlet? Mmmh... err...</td>
<td>I mean, basically, I am not sure. Outlet?</td>
<td></td>
</tr>
<tr>
<td>TRIP</td>
<td>And I am always encouraging her to buy. Only the best for us, right Grace?</td>
<td>I am not sure. I will fix us some drinks. I fully just loaded the bar with rather real quality.</td>
<td>Let’s not go overboard with the drink preparation.</td>
<td>I am not kind of sure. I will fix us some drinks, you know, you see?</td>
<td></td>
</tr>
<tr>
<td>GRACE</td>
<td>Trip, let’s not get too carried away here.</td>
<td>I am not sure. Mmmh... let’s not go overboard with the drink preparation! The kind of funny thing is, Trip doesn’t even like the taste of alcohol.</td>
<td>I fully just loaded the bar with rather real quality.</td>
<td>I fully just loaded the bar with quite real quality.</td>
<td></td>
</tr>
<tr>
<td>TRIP</td>
<td>Aha! Great! I will fix us some drinks. Good news, I just fully loaded the bar, with the real quality.</td>
<td>I am not sure. Mmmh... I see, I will fix us some drinks. I fully just loaded the bar with rather real quality.</td>
<td>The funny thing is. Trip doesn’t even like the taste of alcohol.</td>
<td>I am not sure.</td>
<td></td>
</tr>
<tr>
<td>GRACE</td>
<td>Trip, please... let’s not go overboard with the drink preparation. The funny thing is, Trip doesn’t even like the taste of alcohol.</td>
<td>I am not sure.</td>
<td>I am not sure. I mean, let’s not go overboard with the drink preparation.</td>
<td>I am not kind of sure. I will fix us some drinks, you know, you see?</td>
<td></td>
</tr>
<tr>
<td>TRIP</td>
<td>How about you Grace, can I pour you a glass? I assume you want your usual... ‘a lovely, very cold glass of Chardonnay’.</td>
<td>I am not sure. Mmmh... I am not sure. I mean, let’s not get too carried away here.</td>
<td>I am not sure.</td>
<td>I am not sure. Err... I mean, let’s not go overboard with the drink preparation.</td>
<td></td>
</tr>
<tr>
<td>GRACE</td>
<td>Um, I’d like a simple glass of Chardonnay, thank you.</td>
<td>I am not sure. I mean, let’s not get too rather carried away here mate!</td>
<td>The kind of funny thing is. Trip doesn’t even like the taste of alcohol, pal.</td>
<td>The funny thing is. Trip doesn’t even like the taste of alcohol.</td>
<td></td>
